IO
Haskell and Cryptocurrencies

Dr. Andres Löh, Well-Typed LLP
Dr. Lars Brünjes, IOHK

2018-01-10

Goals

- Recap: explicit effects.
- Simple IO programs.
- Building larger IO programs.
- Reconciling IO and the functional style.

Explicit effects

- Given lazy evaluation as a strategy, the moment of evaluation is not easy to predict and hence not a good trigger for side-effecting actions.
- Even worse, it may be difficult to predict whether a term is evaluated at all.
- We would like to keep equational reasoning, and allow compiler optimisations such as
  - strictness analysis – evaluating things earlier than needed if they will definitely be needed, or
  - speculative evaluation – evaluating things even if they might not be needed at all.

Assume for the time being:

```
getLine :: String
```

Assume for the time being:

```
getLine :: String
```

```
program1 = getLine ++ getLine
program2 = (\ x -> x ++ x) getLine
program3 = (\ x y -> y ++ x) getLine getLine
```

- We can see via the type of a program whether it is guaranteed to have no side effects, or whether it is allowed to use effects.
- In principle, we can even make more fine-grained statements than just yes or no, by allowing just specific classes of effects.
- Encourages a programming style that keeps as much as possible effect-free.
- Makes it easier to test programs, or to run them in a different context.

```haskell
data IO a   -- abstract
```

The type of plans to perform effects that ultimately yield an `a`.

```haskell
data IO a  -- abstract
```

The type of plans to perform effects that ultimately yield an `a`.

- Evaluation does not trigger the actual effects. It will at most evaluate the plan.
- Execution triggers the actual effects. Executing a plan is not possible from within a Haskell program.

```
main :: IO ()
```

- The entry point into the program is a plan to perform effects (a possibly rather complex one).
- This is the one and only plan that actually gets executed.

```
data () = ()   -- special syntax
```

Constructor:

```
() :: ()
```

- A type with a single value (nullary tuple).
- Often used to parameterize other types.
- A plan for actions with no interesting result: `IO ()`.

For convenience, GHCi also executes IO actions:

```
GHCi> getLine
Some text.
"Some text."
```

```
getLine :: IO String
```

A plan that when executed, reads a line interactively and returns that line as a `String`.

GHCi does not print the final result of `IO ()`-typed actions:

```
GHCi> writeFile "test.txt" "Hello"
GHCi> putStrLn "two\nlines"
two
lines
```

```
writeFile :: FilePath -> String -> IO ()
putStrLn :: String -> IO ()
```

Constructing larger plans

```
(>>) :: IO a -> IO b -> IO b
```

Function that takes two plans and constructs a plan that first
executes the first plan, discard its result, then executes the
second plan, and returns its result.

```
getTwoLines :: IO String
getTwoLines = getLine >> getLine
```

```
getTwoLines :: IO String
getTwoLines = getLine >> getLine
```

```
GHCi> getTwoLines
Line 1.
Line 2.
"Line 2."
```

Modifying the result of a plan

```
liftM :: (a -> b) -> IO a -> IO b
```

Takes a function and a plan. Constructs a plan that executes the given plan, but before returning the result, applies the function.

```
duplicateLine :: IO String
duplicateLine = liftM (\ x -> x ++ x) getLine
```

Modifying the result of a plan

```
liftM :: (a -> b) -> IO a -> IO b
```

Takes a function and a plan. Constructs a plan that executes the given plan, but before returning the result, applies the function.

```
duplicateLine :: IO String
duplicateLine = liftM (\ x -> x ++ x) getLine
```

```
GHCi> duplicateLine
Hello
"HelloHello"
```

```
GHCi> :t toUpper
toUpper :: Char -> Char
GHCi> toUpper 'x'
'X'
GHCi> liftM (map toUpper) getLine
Hello
"HELLO"
```

Combining the output of two sequenced plans

```haskell
liftM2 :: (a -> b -> c) -> IO a -> IO b -> IO c
```

Takes an operator and two plans. Constructs a plan that executes the two plans in sequence, and uses the operator to combine the two results.

```haskell
joinTwoLines :: IO String
joinTwoLines = liftM2 (++) getLine getLine
```

Combining the output of two sequenced plans

```
liftM2 :: (a -> b -> c) -> IO a -> IO b -> IO c
```

Takes an operator and two plans. Constructs a plan that executes the two plans in sequence, and uses the operator to combine the two results.

```
joinTwoLines :: IO String
joinTwoLines = liftM2 (++) getLine getLine
```

```
GHCi> joinTwoLines
Hello
world
"Helloworld"
```

```
flipTwoLines :: IO String
flipTwoLines =
  liftM2 (\ x y -> y ++ x) getLine getLine
```

Joining and flipping two lines

```haskell
flipTwoLines :: IO String
flipTwoLines =
  liftM2 (\ x y -> y ++ x) getLine getLine
```

```
GHCi> flipTwoLines
Hello
world
"worldHello"
```

Revisiting the problematic examples

Wrong:

```
program1 = getLine ++ getLine
program2 = (\ x -> x ++ x) getLine
program3 = (\ x y -> y ++ x) getLine getLine
```

Revisiting the problematic examples

Wrong:

```
program1 = getLine ++ getLine
program2 = (\ x -> x ++ x) getLine
program3 = (\ x y -> y ++ x) getLine getLine
```

Better:

```
joinTwoLines1 = liftM2 (++) getLine getLine
joinTwoLines2 = (\ x -> liftM2 (++) x x) getLine
joinTwoLines3 =
  (\ x y -> liftM2 (++) y x) getLine getLine

duplicateLine = liftM (\ x -> x ++ x) getLine

flipTwoLines  =
  liftM2 (\ x y -> y ++ x) getLine getLine
```

Actions that depend on the results of earlier actions

Bind: letting an action use an earlier result

```
(>>=) :: IO a -> (a -> IO b) -> IO b
```

Shouting back

Transforms the result (but does not print it back):

```haskell
shout :: IO String
shout = liftM (map toUpper) getLine
```

Transforms the result (but does not print it back):

```
shout :: IO String
shout = liftM (map toUpper) getLine
```

```
shoutBack :: IO ()
shoutBack = shout >>= putStrLn
```

Shouting back

Transforms the result (but does not print it back):

```
shout :: IO String
shout = liftM (map toUpper) getLine
```

```
shoutBack :: IO ()
shoutBack = shout >>= putStrLn
```

```
(>>=)              :: IO a -> (a -> IO b) -> IO b
shout              :: IO String
putStrLn           :: String -> IO ()
shout >>= putStrLn :: IO ()
```

```
shoutBackTwice :: IO ()
shoutBackTwice =
  shout >>= \ x -> putStrLn x >> putStrLn x
```

```
GHCi> shoutBack
Hello
Hello
```

```
GHCi> shoutBackTwice
can you hear me?
CAN YOU HEAR ME?
CAN YOU HEAR ME?
```

```
return :: a -> IO a
```

An plan that when executed, perform no effects and returns
the given result.

```
return :: a -> IO a
```

An plan that when executed, perform no effects and returns
the given result.

- Intuitively, `IO a` says that we may use effects to obtain
  an `a`. We are not required to.
- On the other hand, `a` says that we must not use effects
  to obtain an `a`.

No escape from IO!

There is no[1] function

```
runIO :: IO a -> a
```

---

[1]There actually is one, called `unsafePerformIO`, but its use is generally not justified.

No escape from IO!

There is no[1] function

```
runIO :: IO a -> a
```

If a value requires effects to obtain, we should not ever pretend that it does not.

---

[1]There actually is one, called `unsafePerformIO`, but its use is generally not justified.

```
(>>=) :: IO a -> (a -> IO b) -> IO b
```

- Gives us access to the `a` that results from the first action.
- But wraps it all up in another `IO` action.

Bind is the most general sequencing function

```
(>>) :: IO a -> IO b -> IO b
a1 >> a2 = a1 >>= \ _ -> a2
```

Bind is the most general sequencing function

```
(>>) :: IO a -> IO b -> IO b
a1 >> a2 = a1 >>= \ _ -> a2
```

Or:

```
(>>) :: IO a -> IO b -> IO b
ioa >> iob = ioa >>= const iob

const :: a -> b -> a
const a b = a
```

Bind and return can implement lifting

```
liftM :: (a -> b) -> IO a -> IO b
liftM f ioa = ioa >>= \ a -> return (f a)
```

```
liftM2 :: (a -> b -> c) -> IO a -> IO b -> IO c
liftM2 f ioa iob =
  ioa >>= \ a -> iob >>= \ b -> return (f a b)
```

do notation

```
liftM2 :: (a -> b -> c) -> IO a -> IO b -> IO c
```

```
liftM2 f ioa iob =
  ioa >>= \ a ->
  iob >>= \ b ->
  return (f a b)
```

```
liftM2 :: (a -> b -> c) -> IO a -> IO b -> IO c
```

```
liftM2 f ioa iob =          liftM2 f ioa iob = do
  ioa >>= \ a ->              a <- ioa
  iob >>= \ b ->              b <- iob
  return (f a b)             return (f a b)
```

```haskell
greeting :: IO ()
greeting =
  putStrLn "What is your name?" >>
  getLine                          >>= \ name ->
  putStrLn "Where do you live?" >>
  getLine                          >>= \ loc ->
  let
    answer
      | loc == "Barbados" = "Fantastic!"
      | otherwise         = "Sorry, don't know that."
  in
    putStrLn answer
```

```haskell
greeting :: IO ()
greeting = do
  putStrLn "What is your name?"
  name <- getLine
  putStrLn "Where do you live?"
  loc <- getLine
  let
    answer
      | loc == "Barbados" = "Fantastic!"
      | otherwise         = "Sorry, don't know that."
  putStrLn answer
```

Functional programming with IO

```haskell
ask :: String -> IO String
ask question = do
  putStrLn question
  getLine
```

```
ask :: String -> IO String
ask question = do
  putStrLn question
  getLine
```

```
GHCi> ask "What is your name?"
What is your name?
Andres
"Andres"
```

```haskell
askMany :: [String] -> IO [String]
askMany []      = return []
askMany (q : qs) = do
  answer  <- ask q
  answers <- askMany qs
  return (answer : answers)
```

The standard design pattern on lists is back!

Feels like a map

A `map` has the wrong result type:

```haskell
askMany' :: [String] -> [IO String]
askMany' = map ask
```

A `map` has the wrong result type:

```
askMany' :: [String] -> [IO String]
askMany' = map ask
```

But we can sequence a list of plans:

```
sequence :: [IO a] -> IO [a]
sequence []       = return []
sequence (x : xs) = do
  a  <- x
  as <- sequence xs
  return (a : as)
```

Mapping an IO action

```
mapM :: (a -> IO b) -> [a] -> IO [b]
mapM f xs = sequence (map f xs)
```

```
mapM :: (a -> IO b) -> [a] -> IO [b]
mapM f xs = sequence (map f xs)
```

```
askMany :: [String] -> IO [String]
askMany questions = mapM ask questions
```

Traversing a tree interactively

A tree of yes-no questions

```
data Interaction =
    Question String Interaction Interaction
  | Result String
```

Constructors:

```
Question ::
  String
   -> Interaction -> Interaction -> Interaction
Result   :: String -> Interaction
```

Pick a language

```haskell
pick :: Interaction
pick =
  Question "Do you like FP?"
    (Question "Do you like static types?"
      (Result "Try OCaml.")
      (Result "Try Clojure.")
    )
    (Question "Do you like dynamic types?"
      (Result "Try Python.")
      (Result "Try Rust.")
    )
```

```
ford :: Interaction
ford =
  Question "Would you like a car?"
    (Question "Do you like it in black?"
      (Result "Good for you.")
      ford
    )
    (Result "Never mind then.")
```

Asking a Boolean question

```haskell
askBool :: String -> IO Bool
askBool question = do
  putStrLn (question ++ " [yn]")
  x <- getChar
  putStrLn ""
  return (x `elem` "yY")
```

```haskell
interaction :: Interaction -> IO ()
interaction (Question q y n) = do
  b <- askBool q
  if b then interaction y else interaction n
interaction (Result r) = putStrLn r
```

```
simulate :: Interaction -> [Bool] -> Maybe String
simulate (Question _ y _) (True  : bs) =
  simulate y bs
simulate (Question _ _ n) (False : bs) =
  simulate n bs
simulate (Result r) []                 = Just r
simulate _              _              = Nothing
```

Acquiring and releasing resources

```
readFile  :: FilePath -> IO String
writeFile :: FilePath -> String -> IO ()
```

Handle-based file IO

All in `System.IO`:

```
hGetLine   :: Handle -> IO String
hPutStrLn :: Handle -> String -> IO ()
hIsEOF    :: Handle -> IO Bool
```

Handle-based file IO

All in `System.IO` :

```haskell
hGetLine   :: Handle -> IO String
hPutStrLn  :: Handle -> String -> IO ()
hIsEOF     :: Handle -> IO Bool
```

```haskell
withFile ::
  FilePath -> IOMode
   -> (Handle -> IO r)  -- continuation (aka callback)
   -> IO r
```

```haskell
data IOMode =
     ReadMode | WriteMode
   | AppendMode | ReadWriteMode
```

Reading a file line by line

```
readFileLineByLine :: FilePath -> IO [String]
readFileLineByLine file =
  withFile file ReadMode readFileHandle

readFileHandle :: Handle -> IO [String]
readFileHandle h = do
  eof <- hIsEOF h
  if eof
    then return []
    else do
      line <- hGetLine h
      lines <- readFileHandle h
      return (line : lines)
```

Handle is automatically released at end of continuation.

Warning

Both `readFile` and `readFileLineByLine` are actually problematic for different reasons.

We will learn about better ways to process (in particular large) files later in the course.

Exceptions

What happens if the file does not exist?

```
GHCi> readFileLineByLine "doesnotexist"
*** Exception: doesnotexist: openFile: does not exit
(No such file or directory)
```

Exceptions in pure code (via `error`, missing patterns, …) are bad:

- It is unclear when exactly, or if, they will be triggered,
- It is therefore also unclear where or when to best handle them,
- Explicitly handling failure via `Maybe` or similar is almost always the better solution.

Exceptions in effectful vs effect-free code

Exceptions in pure code (via `error`, missing patterns, …) are bad:

- It is unclear when exactly, or if, they will be triggered,
- It is therefore also unclear where or when to best handle them,
- Explicitly handling failure via `Maybe` or similar is almost always the better solution.

Exceptions in effectful (`IO`) code are different:

- Execution order is explicit, and handling is easier.
- There are *many* things that go wrong.

From `System.IO.Error`:

```
catchIOError :: IO a -> (IOError -> IO a) -> IO a
```

Catching IO errors

From `System.IO.Error`:

```
catchIOError :: IO a -> (IOError -> IO a) -> IO a
```

```
readFileLineByLine' ::
  FilePath -> IO (Maybe [String])
readFileLineByLine' file =
  catchIOError
    (liftM Just (readFileLineByLine file))
    (const (return Nothing))
```

```
GHCi> writeFile "test" "foo\nbar"
GHCi> readFileLineByLine' "test"
Just ["foo", "bar"]
GHCi> removeFile "test"
GHCi> readFileLineByLine' "test"
Nothing
```

From `System.Directory`:

```
removeFile :: FilePath -> IO ()
```

- The role of the `IO` type.
- Composing `IO` functions.
- Higher-order `IO` functions (`sequence` , `mapM`).
- File IO.
- Resources.
- Exceptions.
